Sentence Structure

Why do we need sentence structure?

We need to understand structure to interpret language correctly, the more information we need to convey, the more words are needed. Without structure, these words will become confusing (especially to computers).

There are two main ways to view words in a language (not only in English)

1. Context-free grammars (Phrase structure grammar)

Phrase structure organizes words into nested constituents.

i.e. building nested blocks that we can use to describe a sentence

Word	Called	Referred to as
the / a	Determiner	Det
cat / dog	Noun	N
large / small	adjectives	Adj

All of these combined form a new thing called **Noun Phrase**

Sentence	Blocks	Called
The (large) dog	Det (Adj) N	Noun Phrase (NP)

Notice that the adjective may or may not be there.

We can then introduce prepositions

Word	Called	Referred to as
by / in / at	Preposition	Prep

When we introduce prepositions, we see that there are new sentences that can be formed.

Sentence	Blocks	Called
in a crate	Prep NP	Prepositional Phrase (PP)

N.B. Notice that we used a compound structure (NP) to form another compound structure (PP). This shows that these are nested components.

With these few structures, we can make an infinite number of sentences.

i.e. The dog in a crate on the table by the kitchen in the house etc

NP PP where each PP contains a new NP which makes it an infinite series of sentences.

We can then introduce new components to make even bigger sentences

Word	Called	Referred to as
talk / walk	Verb	V

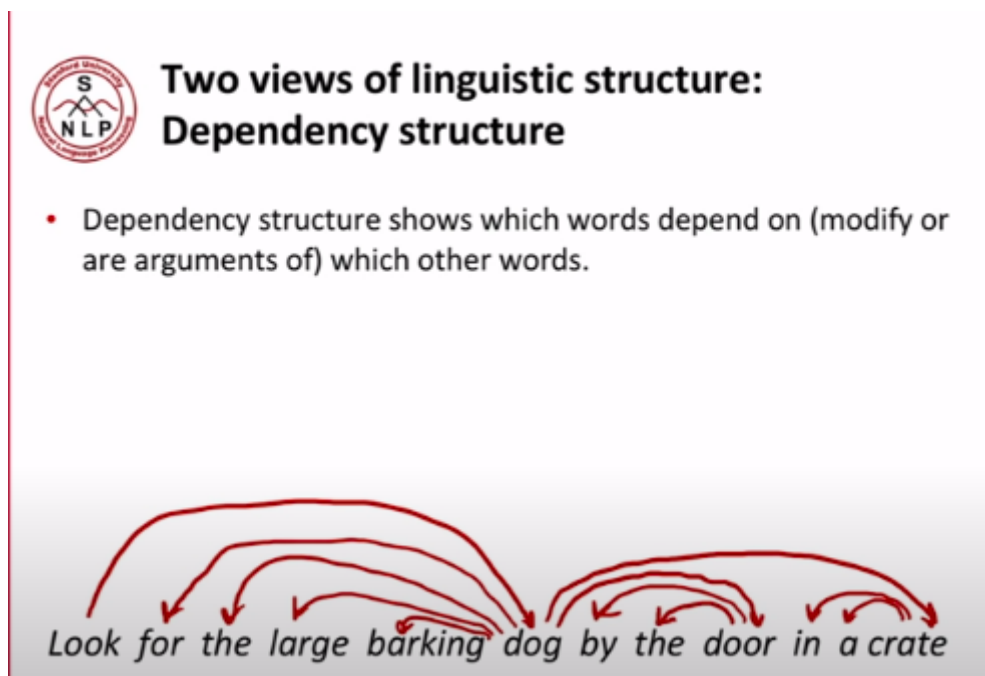

We can use verbs to make **Verb Phrases**

Sentence	Blocks	Called
talk to the cat	V PP	Verb Phrases (VP)

N.B. Different languages will have different components, like may in another language, the **VP** will consist of PP V instead of V PP.

2. Dependency Structure

Dependency structure shows which words **depend on** (modify or are arguments of) which other words.

root: is where the sentence starts, in this case the verb Look

San Jose cops kill man with knife

Ex-college football player, 23, shot 9 times allegedly charged police at fiancée's home

By Hamed Alekovic and Virtan Ho

A man fatally shot by San Jose police officers while allegedly charging at them with a knife was a 23-year-old former football player at De Anza College in Cupertino who was distraught and depressed, his family said.

Thursday, Police officials said two officers opened fire Wednesday afternoon on Phillip Watkins outside his fiancée's home because they feared for their lives. The officers had been drawn to the home, officials said, by a 911 call reporting an armed home invasion.

that, it turned out, had been made by Watkins himself. But the mother of Watkins' fiancée, who also lives in the home on the 4300 block of Sherman Street, said she witnessed the shooting and described it as necessary. Page Buchanan said the confrontation happened shortly after she called a suicide intervention hotline in hopes of getting Watkins medical help.

Watkins' 911 call came in at 5:08 p.m., said Sgt. Heather Randal, a San Jose police spokeswoman. "The officer stated there was a male breaking into his home armed with a knife," Randal said. "The caller also stated he was locked in an upstairs bedroom with his children and requested help from police."

She said Watkins was on the sidewalk in front of the home when two officers got there. He was holding a knife with a 4-inch blade and ran toward the officers in a threatening manner, Randal said.

"Both officers ordered the suspect to stop and drop the knife," Randal said. "The suspect continued to charge the officers with the knife in his hand. Both officers, fearing for their safety and defense of their life, fired at the suspect."

On the police radio, one officer said, "We have a male with a knife. He's walking toward us."

"Shots fired! Shots fired!" an officer said moments later.

A short time later, an officer reported, "Made it down. Knife's still in hand."

Buchanan said she had been prompted to call the Sheriff's Office on 911.

Here the word **kill** has an **nmod** which is called an **instructional modifier** to indicate that the knife was the tool that was used to do the killing

Ambiguities in English parsing

Prepositional phrase attachment ambiguity

This is one of the most common ambiguity in the parsing of English.

When you have a NP or a VP followed by multiple PPs, Those PPs can modify either the Verb or the Noun which leads to the ambiguity

The number of possibilities of the modification is represented by what's called *Catalan numbers*: $C_n = \frac{2n!}{(n+1)!(n)!}$ which have exponential complexity.

These numbers get very high which is the reason for the ambiguity.

There are also many other types of Ambiguities.

Christopher Manning

2. Dependency Grammar and Dependency Structure

Dependency syntax postulates that syntactic structure consists of relations between lexical items, normally binary asymmetric relations ("arrows") called **dependencies**

```

graph TD
    submitted --> Bills
    submitted --> were
    submitted --> Brownback
    Bills --> ports
    ports --> on
    ports --> and
    ports --> immigration
    Brownback --> by
    Brownback --> Senator
    Brownback --> Republican
    Republican --> Kansas
    Kansas --> of
  
```

These are the types of dependency structure that we will try to generate using NNs, so we don't say the type of relationships between each word.

Usually, dependencies form a tree (**connected, acyclic, single-head**).

Building dependency parsers

What do we (humans) look for when doing dependency parsing?

1. **Bilexical affinities** : [discussion --> issues]

This means that certain words are more likely to modify each other

2. **Dependency distance**:

Dependency happens **mostly** with nearby words

3. **Intervening material**:

Dependencies rarely span intervening verbs or punctuation

i.e. you will rarely find a dependency from something that is mentioned before and something after a semi-colon or the word so.

4. **Valency of heads**:

How many dependents are on which side of a word.

i.e. **was completed** there will be a dependency before this (item being completed) but there won't be any nouns after it.

Dependency Parsing

When doing dependency parsing, we have some **constraint**:

- Only one word is a dependent of **ROOT**
- Don't want cycles

This results in the dependency being a tree.

We also want to determine whether or not arrows can cross each other. If they can cross, they are called **non projective**.

Methods of Dependency Parsing

1. Dynamic programming
2. Graph algorithms
3. Constraint Satisfaction
4. **"Transition-based parsing" or "deterministic dependency parsing"**

We will discuss only the 4th one in the course.

"Transition-based parsing" or "deterministic dependency parsing"

Greedy choice of attachments guided by good machine learning classifiers has proven highly effective.

It is inspired by a *shift reduce parser*

Look at the (has time stamp as query parameter) [video](#)

To summarize, we have two items

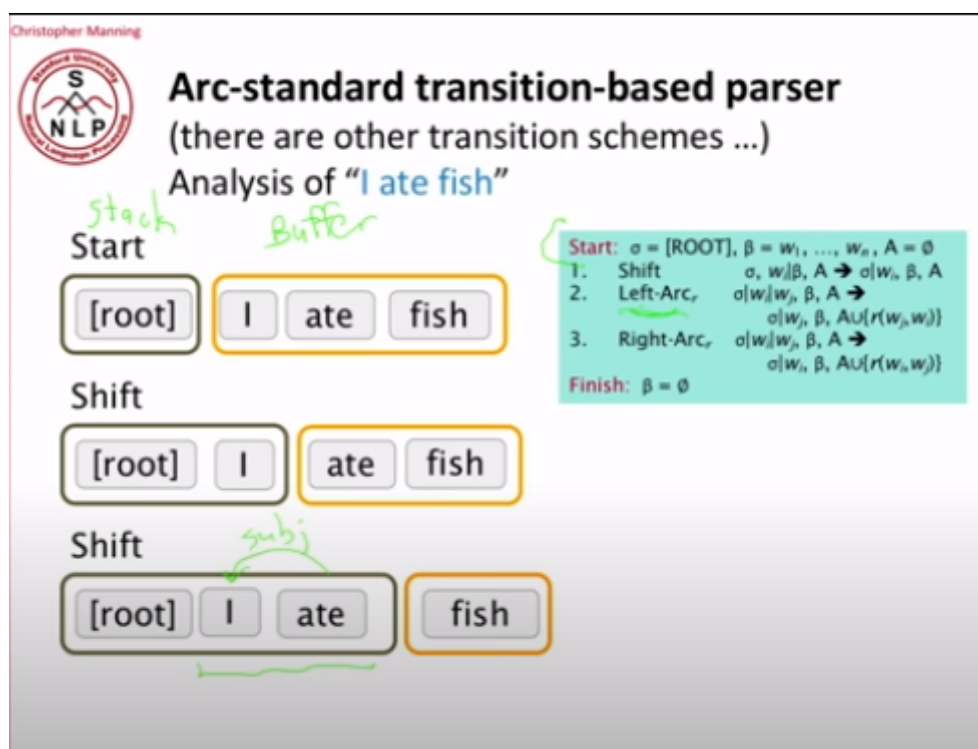

- a **stack**
- a **buffer**

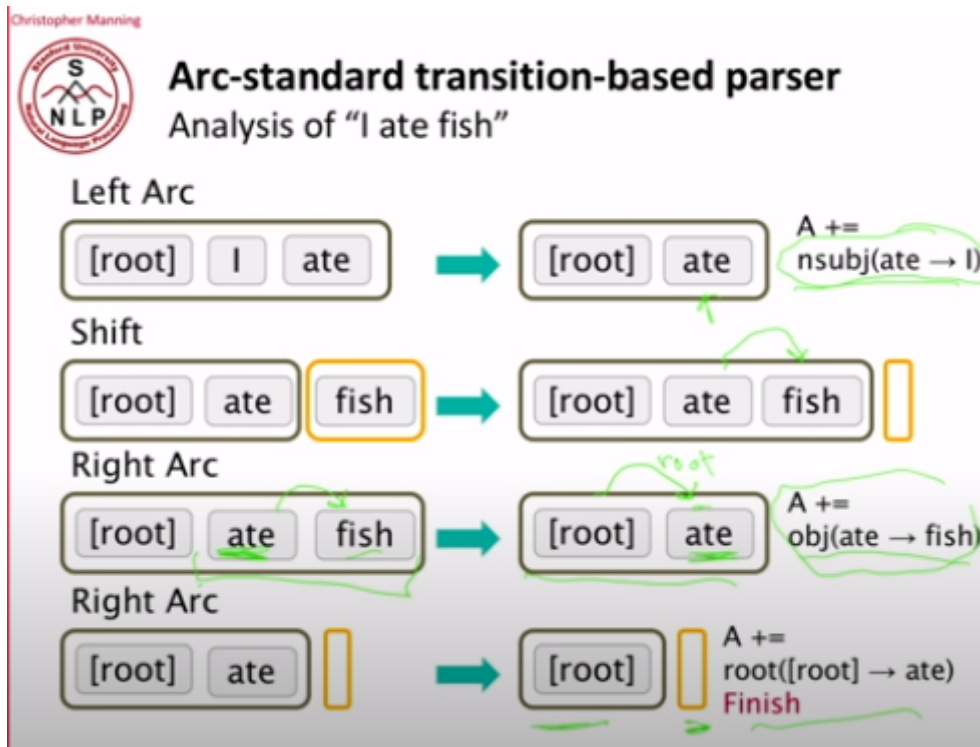

three operations

- **Shift**: move item from the leftmost position in the buffer into the stack
- **Left-Arc reduction**: take the second from top thing on the stack as a dependent of the thing on top of the stack and the head is left on the stack
- **Right-Arc reduction**: take the top thing on the stack as a right dependent to the thing that is second on top of the stack

We use machine learning to train a model that takes decisions in order to decide whether we should do **shift**, **right-arc** or **left-arc**.

Shift reduce parser example

MaltParser

- This was a high accuracy classifier.
- It provides very **fast linear time parsing**.
- Each action is predicted by a discriminative classifier(e.g. softmax classifier) for each move.
- This has no search, However adding **beam search** can bump up the performance of the model

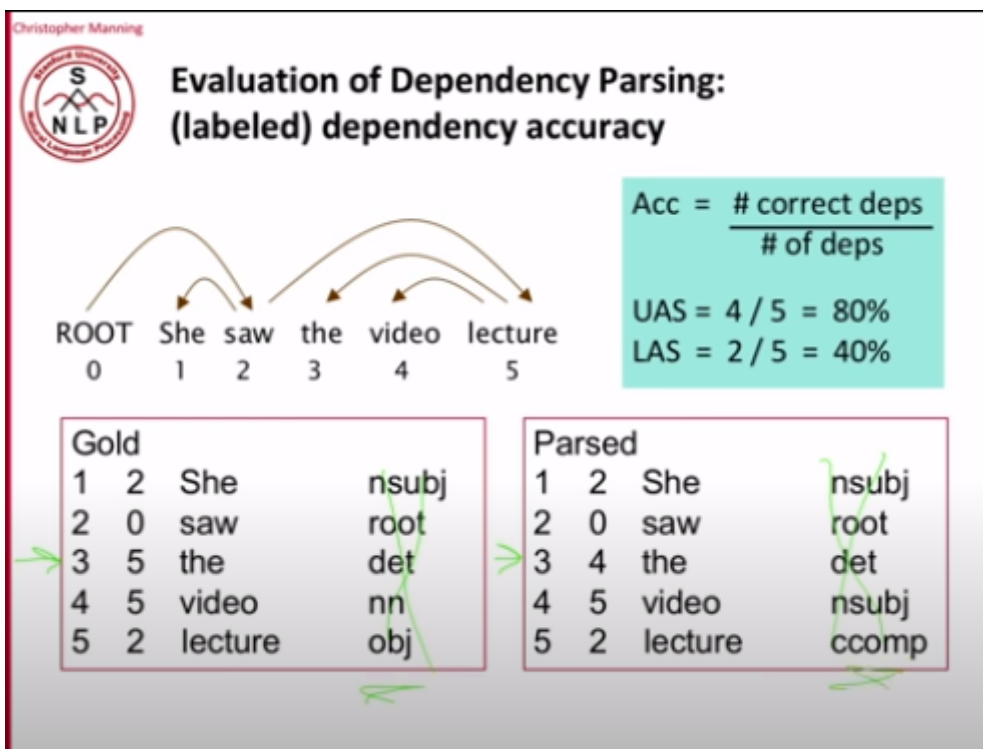

The problem was that the **feature representation** was hard to do in the parsers. You would end up with a binary and sparse $10^6 \sim 10^7$ dimensional matrix which took a lot of time to compute

Problems with Feature Representation

1. **Sparse**
2. **Incomplete**
3. **Expensive** computation: More than 95% of parsing time is consumed by feature computation.

This motivated **neural dependency parsers** where the feature representation is replaced by a neural network to learn these features on its own.

Evaluation of dependency parsers

There are two metrics:

- **Unlabeled Attachment Score (UAS):** This checks the arrows only ignoring the labels
- **Labeled Attachment Score (LAS):** This checks the labels and the arrows

Neural dependency parser

The thing that makes them succeed is that the time taken to compute the matrices is way less than the time taken to compute features in the non neural parsers.

Distributed Representations

- **Words**

Words were represented as d -dimensional vectors (word embeddings)

- **POS and dependency labels**

They were also represented as d -dimensional vectors.

Part of speech (POS)

NNS(Plural Noun) should be close to **NN**(singular noun)

Dependency Labels

num (numerical modifier) should be close to **amod** (adjective modifier).

We convert the words and their pos and dependency labels into a the feature as follows.

Model Architecture

Improvements made to dependency parsers

- Bigger, deeper networks with better tuned hyperparameters
- Beam search
- Global, conditional random field (CRF)-style inference over the decision sequence.
